PREFACE

The work described in this report was performed by the Tracking and Data Acquisition organizations of the Jet Propulsion Laboratory, Air Force Eastern Test Range, Manned Space Flight Network, and the NASA Communications Network of Goddard Space Flight Center. This volume covers the Tracking and Data System activities in support of the Mariner Mars 1971 Project for orbital operations, which includes the period from orbit insertion to end of primary mission. Tracking and Data System flight support, performance evaluation, and configuration are described.

ACKNOWLEDGMENT

The authors acknowledge the considerable assistance of the NASA Communications Network of the Goddard Space Flight Center and the Deep Space Network (DSN) of the Jet Propulsion Laboratory in providing tracking and data support. Information regarding the DSN is based on material generated by the DSN Interface Team for the Mariner Mars 1971 Project, the DSN Operations Staff, and the monthly DSN Operations Reports. The following persons made significant contributions:

D. W. H. Johnston	Deep Space Stations Operations Support
T. W. Howe	Assistant
W. G. Meeks	Assistant
J. W. Capps	GCF Communications
M. D. Weidner	Assistant
L. E. Jennings	SFOF Data Systems
B. M. Hayes	SFOF Support
L. R. Stevens	DSN Scheduling
C. W. Harris	Telemetry System
R. B. Miller	Tracking System
W. G. Stinnett	Command System
J. E. Allen	Monitor System
R. Santiestevan	DSN Operations Reports

Information relative to the mission and the spacecraft was obtained from the Mariner Mars 1971 Project Reports. The authors are indebted to A. C. Belcher and M. E. Binkley of NASA Headquarters for their support. Appreciation is expressed to H. M. Yamamoto of the JPL Publications Section and to J. A. Bain of the Tracking and Data Acquisition Documentation Group for their assistance in preparing this document.

ABSTRACT

This volume of the Tracking and Data System (TDS) Support for the Mariner Mars 1971 Mission final report contains the deep space tracking and data acquisition activities in support of orbital operations, which include the period from orbit insertion (November 14, 1971) to end of primary mission (April 1, 1972). During this period (February 12, 1972), a major NASA objective was accomplished: completion of the 180th revolution and 90th day of data gathering with the spacecraft about the planet Mars. Included are presentations of the TDS flight support pass chronology data for each of the Deep Space Stations used, and performance evaluation for the Deep Space Network Telemetry, Tracking, Command, and Monitor Systems. With the loss of Mariner 8 at launch, Mariner 9 assumed the mission plan of Mariner 8, which included the TV mapping cycles and a 12-hr orbital period. The mission plan was modified as a result of a severe dust storm on the surface of Mars, which delayed the start of the TV mapping cycles until January 3, 1972. Thus, the end of primary mission date was extended to April 1, 1972 to complete the TV mapping cycles.

I. INTRODUCTION

A. Purpose

This document, Volume III of the Tracking and Data System (TDS) Support for the Mariner Mars 1971 (MM'71) Mission, summarizes deep space tracking and data acquisition activities in support of orbital operations of the Mariner Mars 1971 Mission from orbit insertion (November 14, 1971) to end of primary mission (April 1, 1972). With the previously completed Volumes I and II, together with Volume IV, this report constitutes the complete history of TDS activities supporting MM'71.

B. Scope

Volume III contains a description of TDS flight support of orbital operations from orbit insertion to end of primary mission (Section III). TDS requirements (Section I), TDS plan and configuration (Section II), and TDS performance and evaluation (Section III) are also included.

Volume I covers TDS support of prelaunch testing and training for both near-Earth and deep space phases (Section IV) and TDS flight support from launch operations through first trajectory correction maneuver (Section V). TDS requirements (Section II), TDS plan and configuration (Section III), and performance evaluation (Section V) are also included.

Volume II describes TDS flight support from the first trajectory correction maneuver through the end of the cruise period and orbit insertion (Section III), plus TDS support of preorbital testing and training (Section IV). TDS requirements (Section I), TDS plan and configuration (Section II), and TDS performance and evaluation (Section III) are also included.

Volume IV will describe the MM'71 Extended Mission TDS support.

C. TDA Function and Organization

The TDA function and organization is presented in the Introduction, Section I, Volume I, and is therefore not covered in this report.

D. TDS Organization

The TDS organization, as described in Volume I, has undergone no changes or additions.

E. TDS Requirements on Project

The DSN required the Project to supply spacecraft/DSS telecommunications interface information in accordance with JPL Document 610-74, Volume II of Operations Plan. The Project was required to supply standards and limits for the DSN Tracking, Telemetry, and Command Systems in accordance with JPL Document 610-75, Revision A, Volume IIB of Operations Plan. The TDS required the Project to conform with NASA Directive 2570.1A, which required all planetary projects to provide their spacecraft with a capability to turn off the RF carrier by command at the completion of the mission.

F. Mission Operations

Mission Operations for MM'71 are presented in Section I of Volume I.

G. Mission Plan

1. General. The MM'71 Mission Plan is the same as that presented in Volume II, except for the modification of Mission Orbit Operations with the Mariner 9 spacecraft as a result of a severe dust storm on the surface of Mars. This dust storm covered most of the surface features of Mars and did not subside sufficiently to start the TV mapping cycles until January 3, 1972. Three complete mapping cycles (TV plus other science)

of about 20 days each, and ending March 1, 1972, plus a "Bi-Cycle" Plan ending April 1, 1972, were incorporated into the Mission Plan. These mapping cycles are covered in detail in Project Document PD 610-16, MP-71-4-200A (Amendment 3), the Bi-Cycle Plan, and the Extended Mission, in addition to Reconnaissance I and II Mission Plan.

The guidelines and profiles for Mission Orbit Operations are as follows:

- (1) Standard Mission Orbit Operations (Volume II), orbits 0-23, 11/14/71 to 11/26/71.
- (2) Recon I Cycle Plan, orbits 24-63, 11/26/71 to 12/16/71.
- (3) Recon II Cycle Plan, orbits 64-99, 12/16/71 to 1/3/72.
- (4) Cycle I Mapping, orbits 100-138, 1/3/72 to 1/22/72.
- (5) Cycle II Mapping, orbits 139-177, 1/22/72 to 2/10/72.
- (6) Cycle III Mapping, orbits 178-216, 2/10/72 to 3/1/72.
- (7) Bi-Cycle Plan, orbits 217-278, 3/1/72 to 4/2/72.
- (8) Extended Mission Plan, 2/12/72 to 12/1/72.

2. Standard Mission Orbit Operations. The guidelines and profile for the Standard Mission Orbit Operations, covered in Volume II, include orbits 0 through 23. A severe dust storm covering most of the surface of Mars was encountered from the start of the TV mapping. This dust storm blotted out most of the surface features and prevented satisfactory TV mapping sequences from being obtained; all other science data were not affected. This condition existed until January 2, 1972, thus causing a replanning of the mapping cycles, including two reconnaissance cycles, through each TV mapping cycle, and one bi-cycle plan.

H. Reconnaissance I Mission Plan Guidelines

The Recon I Mission Plan was outlined as follows:

- (1) Assumes a 30-picture budget.
- (2) The sequences do not change as far as timing is concerned and very little as far as pointing is concerned, except for the targeted B's (tetrads) and limb TV.
- (3) The capability will exist to shutter single B frames at almost any time by direct commands (DCs). Slews for such extra frames (for satellites) shall be QCs. All such frames shall come out of the mapping budgets. Mapping will automatically terminate at end of tape.
- (4) The first revolutions that this plan could be implemented in are revolutions 24 and 25.

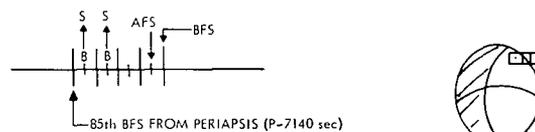

- (5) One CC&S load might run several days without updates.
- (6) The only variable pointing shall be the starting position of:
 - (a) Three IRR terminator scans (2 positions)
 - (b) Tetrad 1
 - (c) Tetrad 2
 - (d) Global TV
 - (e) Limb TV
 - (f) Polar or VSF TV
 - (g) UVS low-rate target
 - (h) UVS high-rate target
 - (i) UVS limb scan
 - (j) IRR limb scan
 - (k) Mapping

Recon I mission profile is shown in Fig. 1.

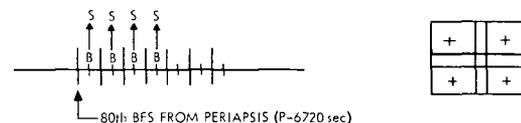

I. Nominal Plan for Zenith Revolutions

The plan for zenith revolutions follows:

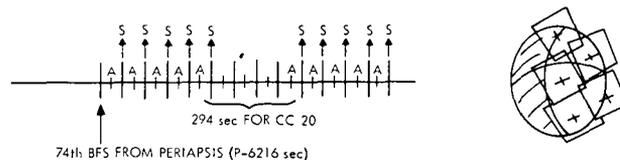

- (1) Slew from reference position (KA 193.0, CA 96.2) to KA&CA of limb TV. Slew begins at 185 min before periapsis (11, 100 sec).
- (2) Limb TV - Two B frames, overlapping, on limb:

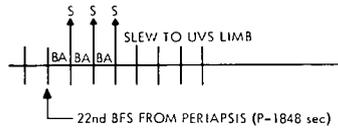

- (3) Tetrad 1 - Overlapping of four B frames on a target (using a standard slew pattern):

- (4) Global TV - Mosaic the lighted disk with five A frames in two colors:

- (5) Tetrad 2 - Same as Tetrad 1, begins on the fifty-seventh BFS from periapsis (P-4788 sec).
- (6) UVS and IRIS pressure mapping as normal.
- (7) Slew to polar TV or VSF position at the twenty-seventh BFS from periapsis (P-2268 sec).
- (8) Polar TV or VSF photography - Take three BA pairs in a standard pattern for both polar and VSF:

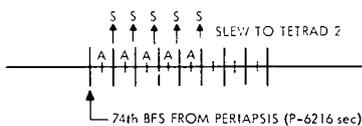

- (9) UVS limb experiment as normal.
- (10) Begin slew to mapping position at the thirteenth BFS from periapsis (P-1092 sec).
- (11) Map - Take two BA pairs or map to end of tape recorder beginning at the tenth BFS from periapsis (P-840 sec). Mapping is done at a fixed CA&KA.
- (12) Begin slew to UVS high-rate target at $P_Z + 12$ min (Lyman- $\alpha 1$).
- (13) Begin slew to UVS low-rate target at $P_Z + 275$ min (Lyman- $\alpha 2$).

J. Nominal Plan for Nadir Revolutions

The plan for nadir revolutions follows:

- (1) Slew from Lyman- $\alpha 2$ (low-rate) to CA&KA of first IRR terminator swath. Slew begins at 61 min from apoapsis.
- (2) Slew to second IRR terminator swath.
- (3) Slew to third IRR terminator swath.
- (4) Limb TV - Same as zenith pass, same timing.
- (5) Tetrad 1 - Same as zenith pass, same timing.
- (6) Global TV - Mosaic lighted disk with five A frames in only one color.

- (7) Tetrad 2 - Same as on zenith pass, begins on sixty-sixth BFS from periapsis (P-5544 sec).
- (8) Slew to begin IRR limb scan at end of tetrad.

- (9) Begin slew to polar or VSF TV position at the twenty-seventh BFS from periapsis (P-2268 sec).
- (10) Polar TV or VSF TV - Same as zenith revolution, same time. When completed begin slew to mapping position. Standard pattern for both polar and VSF TV.
- (11) Map - Take at least four BA pairs + 1 B. Begin same time as on zenith pass.
- (12) Begin slew to reference position (CA 96.2, KA 193.0) at $P_N + 12$ min.

K. Reconnaissance II Mission Plan Guidelines

Recon II Mission Plan follows:

- (1) Assumes 32-picture per revolution tape recorder budget.
- (2) The basic timing and structure of individual links and overall sequences will remain constant from revolution to revolution.
- (3) Optimization of the pointing of certain links will be accomplished periodically. Links that will be considered for such optimization are:
 - (a) Global TV (N and Z)
 - (b) UVS limb scans (Z)
 - (c) UVS/IRR/IRIS morning spectral mapping (Z)
 - (d) IRR morning terminator scans (N)
 - (e) UVS/IRR/IRIS evening spectral mapping (N and Z)
 - (f) TV mapping (N and Z)
- (4) Links that may be considered retargetable on a daily basis are:
 - (a) Tetrads 1 and 2 (Z)
 - (b) Triads 1 and 2 (N)
 - (c) Dyad (N)
 - (d) Sextad (N and Z)
 - (e) Lyman- $\alpha 1$ (high-rate)
 - (f) Lyman- $\alpha 2$ (low-rate)
- (5) Satellite astronomy will be carried out by use of existing targetable links, where possible, without changing the timing and structure of the link, or by ground commanding the shuttering of single B frames or single BA pairs. All slews for such satellite photography will be CC&S-controlled. Satellite frames will automatically reduce the mapping budget by an amount equal to the number of satellite frames in a revolution.
- (6) One CC&S load might run several days without an update.
- (7) Planning for a two-revolution sequence will be completed seven days before the

execution of the sequence by the spacecraft; however, changes will be considered up to three days before execution.

- (8) The first revolutions that this plan could be implemented in are revolutions 64 and 65.

Recon II mission profile is shown in Fig. 2.

L. Cycle I Mission Plan Guidelines

Cycle I Mission Plan follows:

- (1) Assumes 32-picture per revolution tape recorder budget.
- (2) The basic timing and structure of individual links and overall sequences will remain constant from revolution to revolution.
- (3) Optimization of the pointing of certain links will be accomplished periodically. Links that will be considered for such optimization are:
 - (a) Global TV (N and Z)
 - (b) UVS limb scans (Z)
 - (c) UVS/IRR/IRIS morning spectral mapping (Z)
 - (d) IRR morning terminator scans (N)
 - (e) UVS/IRR/IRIS evening spectral mapping (N and Z)
 - (f) TV mapping (N and Z)
- (4) Links that may be considered retargetable on a daily basis are:
 - (a) Pentad (Z)
 - (b) Tetrads (N and Z)
 - (c) Dyads (N)
 - (d) UVS targets
 - (e) TLR
- (5) Satellite astronomy will be carried out by use of existing targetable links, where possible, without changing the timing and structure of the link, or by ground commanding the shuttering of single B frames or single BA pairs. All slews for such satellite photography will be CC&S-controlled. Satellite frames will automatically reduce the northern hemisphere reconnaissance budget by an amount equal to the number of satellite frames in a revolution.
- (6) Planning for a two-revolution sequence will be completed seven days before the execution of the sequence by the spacecraft; however, changes will be considered up to three days before execution.

- (7) The first revolutions that this plan could be implemented in are revolutions 100 and 101.

Cycle I mission profile is shown in Fig. 3.

M. Cycle II Mission Plan Guidelines

Cycle II Mission Plan follows:

- (1) Assumes 32-picture per revolution tape recorder budget with 8-kbps playback to supplement 16-kbps playback of both revolutions. Playback ends at P-60 min.
- (2) The basic timing and structure of individual links and overall sequences will remain constant from revolution to revolution (at least until revolution 142), except for slews identified as floating slews in the detailed orbital sequence plan.
- (3) Optimization of the pointing of certain links will be accomplished periodically. Links that will be considered for such optimization are:
 - (a) UVS limb scans (Z)
 - (b) UVS/IRR/IRIS morning spectral mapping (Z)
 - (c) IRR morning terminator scans (N)
 - (d) UVS/IRR/IRIS evening spectral mapping (N and Z)
 - (e) TV mapping (N and Z)
 - (f) Geodesy (N and Z)
- (4) Links that may be considered retargetable on a daily basis are:
 - (a) Single B frames (SB)
 - (b) Triads (N and Z)
 - (c) UVS targets
- (5) Satellite astronomy will be carried out by use of existing targetable links, where possible, without changing the timing and structure of the link, or by ground commanding the shuttering of single B frames or single BA pairs. All slews for such satellite photography will be CC&S-controlled. Satellite frames will automatically reduce the northern hemisphere reconnaissance budget by an amount equal to the number of satellite frames in a revolution.
- (6) Targeting for SB 1 will periodically be chosen to optimize a UVS limb scan on zenith revolutions.
- (7) Targeting for SB 2 and 3 will be chosen in conjunction with UVPM scans on the zenith revolution and IRR scans on the nadir passes.

- (8) Early tape recorder start capability will be exercised on the nadir pass after the Map 2 sequence.
- (9) Late slew (B-frame shutter + 48 sec) capability will be exercised only on SB 1 on nadir and zenith passes.
- (10) Planning for a two-revolution sequence will be completed seven days before the execution of the sequence by the spacecraft; however, changes will be considered up to three days before execution.
- (11) The first revolutions that this plan could be implemented in are revolutions 139 and 140. Since the mapping cycle is only 39 revolutions long, the last revolution of Cycle II will be 177.

Cycle II mission profile is shown in Fig. 4.

N. Cycle III Mission Plan Guidelines

- (1) This plan assumes a variable picture budget due to the lowering telecommunications margins that occur throughout this cycle. The cycle begins with over 30 pictures per revolution and ends with about 13 or 14 pictures played back per revolution. Two methods to account for the diminishing picture return were assumed. This plan first allowed for one major CC&S update to occur sometime during the cycle to remove selected frames. Secondly, it was assumed that adjustment of the time of playback and position of the recorder for the start of playback could be accomplished on a daily basis to bias which pictures are to be played back. This plan also assumes that playbacks end at the time the planet comes into view.
- (2) The basic timing and structure of the individual links and overall sequences will remain constant from revolution to revolution before and after the one major CC&S update.
- (3) Optimization of the pointing of the TV mapping link will be accomplished periodically.
- (4) Links that may be considered retargetable on a daily basis are:
 - (a) Tetrads and dyads (N and Z)
 - (b) T.E.C. (Z)
 - (c) UVS limb scans (Z)
 - (d) UVS/IRR/IRIS spectral scans (N and Z)

(e) UVS Lyman- α targets

- (5) Satellite astronomy or other target photography will be carried out by use of existing targetable links, where possible, without changing the timing and structure of the link, or by ground commanding the shuttering of single B frames or single BA pairs. All slews for such satellite and additional target photography will be CC&S-controlled. These frames will automatically reduce the northern hemisphere reconnaissance budget by an amount equal to the number of such frames in a revolution.
- (6) Early tape recorder start capability for A frames will exist for the entire nadir and zenith revolution sequences; however, this capability will be exercised at the beginning of the cycle only on the nadir pass.
- (7) While this plan does not specifically include a floating dyad, this link is desirable for the last part of Cycle III. A floating dyad, two B frames on a single target, would replace Dyad 1 and Tetrad 1 on the zenith pass and Dyad 1 and Dyad 2 on the nadir pass. It is assumed that this floating dyad would be fixed in either one of two possible times on a daily basis.
- (8) Planning for a two-revolution sequence will be completed seven days before the execution of the sequence by the spacecraft; however, changes will be considered up to three days before execution.
- (9) The first revolutions that this plan could be implemented in are revolutions 178 and 179. Since the mapping cycle is only 39 revolutions long, the last revolution of Cycle III will be 216.

Cycle III playback profile is shown in Fig. 5. Cycle IIIa profile (beginning) is shown in Fig. 6.

O. Bi-Cycle Mission Plan Guidelines

The Bi-Cycle Mission Plan extended from the end of the TV Mapping Cycle III (March 11, 1972) to the beginning of Sun occultation (April 2, 1972). For the first 15 days, to March 15, 1972, spacecraft power usage tests were conducted to determine maneuver characteristics. No HGA maneuvers were performed during this period, but TV mapping was conducted on a noninterference basis. An 8-day window was then available to March 23, 1973, when HGA pointing maneuvers were allowed: TV mapping was conducted during this period. The remaining 10 days before April 2, were used only for SCT testing in preparation for the solar occultations.

NOTE:
THE UNDERLINED FRAMES WILL BE DELETED BEFORE THE END OF CYCLE III

Fig. 6. Cycle IIIa profile (beginning)

II. TRACKING AND DATA SYSTEM PLAN AND CONFIGURATION

The Tracking and Data System plan and configuration remained the same as that presented in Volume II of the Tracking and Data System Support for the Mariner Mars 1971 Mission (Section III).

III. TRACKING AND DATA SYSTEM FLIGHT SUPPORT

A. General

Tracking and Data System flight support for Mariner 9 Spacecraft Orbital Operations extended from orbit insertion (November 14, 1971) through the end of the Bi-Cycle Mission Orbit Operations (April 1, 1972). (See Section I, Subsection G, for the Standard Mission Orbit Operations cycle plans, number of orbits, and respective dates.) The Reconnaissance, Mapping, and Bi-Cycle Plans were formulated and placed into operation on January 3, 1972 as a result of the severe dust storm on the surface of Mars, encountered at the time of orbit insertion.

Details of the TDS flight support were obtained from monthly DSN Operations Reports for MM'71. The mission-dependent DSN Operations Organization is described in Volume I. Functional flight support pass chronology data for the DSN are presented in Subsection B. DSN Telemetry, Tracking, and Command Systems analysis and performance evaluations are presented in Subsections C, D, and E.

All times and dates herein are expressed in Greenwich Mean Time (GMT or Z).

B. Flight Support Pass Chronology

1. General. Tracking and Data System flight support included in this volume for Mariner 9 spacecraft orbital operations extended from the end of orbit insertion, 0101Z on November 14, 1971, day 318, through the end of the Bi-Cycle Mission Orbit Operations Plan, orbit 278, April 1, 1972, day 92. For a more complete description of the MM'71 Mission Plan, see Project Document PD 610-16, NP-71-4-22A.

2. Pass chronology data. A total of 139 passes (492 total tracks) were supported during the 4 months and 17 days of this period, during which 32,567 commands were transmitted to the spacecraft.

General performance of all DSN systems supporting the MM'71 Mission was excellent. DSN pass chronology activity is summarized in Table 1. Details of pass chronology are presented in the appendix. Only anomalies affecting the prime data source (the station whose telemetry HSD was being processed by the Central Processing System (CPS) or, if the CPS was not supporting, the station that was two-way during track overlaps) are given in the pass chronology on a pass-by-pass or track-by-track basis. Each anomaly is prefaced by a

facility or system identifier, such as DSS, GCF, or CPS. Anomalies are listed by item number and time of failure and are limited to items that significantly affected mission operations during scheduled DSN flight support (interruptions of real-time data flow or actual data loss to the Project for 5 min or longer).

Configuration deviations that restricted the Project from conducting normal or planned operations commensurate with scheduled DSN support were considered significant and will be found in the pass chronology. Comments listed under deviations or anomalies in the pass chronology were based on real-time observations and indications and did not necessarily reflect nonreal-time followup on items requiring further investigation.

All data outages were considered as real time and recoverable, and data outage times were considered the same as system or equipment down times, unless otherwise indicated.

C. DSN Telemetry System Analysis and Performance

Residual data plots for November 1971, shown in Volume II of the TDS Support for the Mariner 1971 Mission, include the MOI for all stations. Residual data plots of SNR levels, uplink (UL) signal levels, and downlink (DL) signal levels for each station tracking Mariner 9 spacecraft during this reporting period are shown in Figs. 7 through 27. Values plotted were taken at meridian crossing for each pass. The set of plots represents those stations that have actively participated in tracking the Mariner 9 spacecraft during this reporting period. The number of days plotted varies from station to station as a function of individual station tracking schedule. A statistical analysis on absolute data values yielded results detailed in Table 2.

D. DSN Tracking System Analysis and Performance

1. Interface with experimenters

a. Data provided for celestial mechanics experiment. The Tracking System Analysis Group provided data for the celestial mechanics experiment (CME) in the form of a CME tape written in conjunction with the master data records (MDR).

b. Data provided for occultation experiment. The Tracking System Analysis Group.

provided the following data for the occultation experiment:

- (1) A copy of the engineering predicts covering each occultation and a copy of synlo predicts for each station with an open loop receiver.
- (2) Pseudoresiduals for each station participating in the occultation events.
- (3) A project tracking tape (PTT) for each occultation event. Data coverage for each tape was from 10 min prior to enter occultation to approximately 15 min after exit occultation. Tables 3 through 6 show the occultation view period for each station participating.
- (4) Each PTT provided was supplemented with a 1443 printout showing transmitter frequency, data editing, pass summary data, and the first and last physical data record on the tape.

Table 7 shows the tapes provided for the occultation experimenter and the recycle schedule used in providing the tapes.

2. Orbital trim maneuver doppler shift. The orbital trim maneuver necessary to put Mariner 9 into a 12-hr orbit was planned for a ground observed time of 02:43:44 GMT, November 16, 1971. The burn was programmed to last 6.25 sec and to result in a total doppler shift (one-way) of -117.65 Hz. The tracking data were processed by the pseudoresidual program in near real time, and the resulting doppler residuals were hand-plotted as seen in Fig. 28. The doppler residual as produced by the pseudoresidual program appeared to be within 1 Hz of the predicted value.

At the conclusion of the first set of occultations, it was decided to effect a second orbital trim maneuver to increase the period and the periastron altitude. This maneuver was planned for a ground observed time of 21:58:52, December 30, 1972. The burn was programmed to last 17.2 sec and result in a total two-way doppler shift of -596 Hz.

Navigation provided the Tracking System Analysis Group with two probe ephemeris tapes (PETs), one tape without the burn trajectory, and one tape with the burn trajectory included. Predicts were generated using the no-burn probe ephemeris tape. Residuals were computed using the actual observed data minus the no-burn prediction data, thus illustrating the actual burn as it occurred. The doppler residuals as produced by the pseudoresidual program were -595 Hz, or within 1 Hz of the predicted value. Figure 29 shows the orbital trim maneuver burn as it appeared in the data. This display was made available on the predicts status display CCTV. It was another example of the inherent capability of the Tracking System Analysis Group to monitor and display spacecraft events as they appear in the data.

In summary, TDH data were basically good throughout this reporting period. Data losses were caused primarily by disk problems within the 360/75 computer system. The Tracking System Analysis Group was able to provide recovery of 98.5% of data losses by requesting retransmission

of data from the CP or DSS when necessary. With the exception of the disk problems, no major difficulties were experienced in performing DSN tracking analysis activities.

3. TDH data received and processed

a. TDH system. The tracking system gathered and recorded tracking data and transmitted it to the SFOF for use in support of the spacecraft navigation function. As these data were received in the SFOF, it was the responsibility of the Tracking System Analysis Group to validate, edit, store, and process these tracking data so that they may be passed on to the Navigation Group and other users of the DSN.

b. Prime DSS coverage. DSSs 12, 41, 62, and 14 remained the prime DSN stations for the Mariner mission during this reporting period. Due to 360/75 computer software problems, the radio metric data accountability was not 100% reliable for this reporting period.

c. TDH subsystem problem at DSS 12. On December 2, 1971 (day 336), starting at 01:10:00, the TDH subsystem began losing a digit in the day of year (DOY) field, and the problem was not corrected until 03:05:00. Because of this error in the data, it was impossible to process the data taken during this period in the 360/75.

d. Summary of tracking data. Radio metric data received and processed during this period were generally of good quality with very few outages. The basic tracking plan used during this reporting period was two-way doppler tracking with two-way transfers between the prime DSN stations. One-second sample rate requirements by the occultation experimenter account for the large amount of tracking data.

4. Predicts

a. Orbital predicts. Predicts were generated to meet occultation experiment requirements and to obtain good two-way spacecraft acquisition data. The track synthesizer frequency (TSF) and the two-way acquisition logic were determined in near real time by the Tracking System Analysis Group. The TSF and the sequence of events to obtain two-way acquisition were displayed on the predict status CCTV display. Figure 30 is an example of the predicts message displayed. This message contained the TSF to be used for both enter and exit occultation, the transmitter on time, transmitter on frequency, the tuning rate, and tuning span.

b. Significant predict analysis. On day 354 the Navigation Team provided data which indicated that the last occultation would occur on day 357 for the Goldstone Zenith Station. The Tracking System Analysis Group analyzed the data and concluded that one additional occultation had been overlooked by the Navigation Team. After consultation with the Navigation Team concerning this possibility, it was concluded that under the current double-precision trajectory configuration, it was possible to miss small occultations. A new double-precision trajectory run was executed with a smaller event search interval and the existence of one more occultation was proven. This is an example of the valuable technical interfaces that

existed between the various elements of the DSN and the Project.

c. Accuracy of predicts during orbital phase. During orbital phase, the uncertainties in the spacecraft trajectory are far greater than during the cruise phase. The resulting inaccuracies in predicts at times get large enough to be considered bothersome. A simple measure of the predicts error is the value of the doppler residual produced by the pseudoresidual program, since this is merely the raw doppler data minus the predicted doppler data. Two-way doppler residuals were recorded from pseudoresidual output at enter occultation minus 2 hr, the local maximum (peak) near periapsis, enter occultation, exit occultation, and exit occultation plus 2 hr and can be seen in Table 8. The horizontal lines indicate a new PET. As can be seen, the worst PET was the one in use from day 331 to 334, when the maximum doppler residual exceeded 400 Hz and the maximum error in predicted occultation time exceeded 20 sec.

d. Special predicts. Two sets of special predicts were generated for the second orbital trim maneuver: one set using a PET without the burn trajectory, and one set using a PET with the burn trajectory.

e. Summary of predicts. Predicts for this reporting period were very good. Adjustments and biases were made in real time to account for spacecraft events having an effect on frequencies used by the DSN. A total of 98 sets of predicts were generated. Sixty-seven sets were transmitted to the DSSs while the remaining sets were used for special events and for predicts studies.

5. Occultations. The DSN Tracking System Analysis Group provided two areas of support to the occultation experimenter: predicts for the open- and closed-loop receiver, and gathering of the closed-loop data in a form usable by the experimenter.

The closed-loop predicts are the standard tracking predicts with track synthesizer frequencies manually set to optimize acquisition at exit occultation, and to restrict tuning to handovers and exit occultation to minimize data loss. The open-loop predicts are special predicts called synlo.

The tracking data processing provided by the Tracking System Analysis Group consisted of processing one-second TDH data encompassing occultation, using the DSN tracking software subsystem in the 360/75. The processing is no different than that which is provided for the Navigation Team, the final output being a project tracking tape (PTT), except for problems peculiar to handling one-second sample rate TDH. Special procedures which enable the tracking software subsystem to successfully process two streams of one-second TDH at TTY rate (one point per 6 sec) had to be developed in near real time.

The occultation experimenter was unable to process PTTs for the first week of orbital operations because of problems with the occultation software. This resulted in a backlog of over 14 PTTs (two a day, one for Goldstone and one for nadir occultations). This would have been of no consequence except that there were problems with eight of the initial tapes which went undiscovered

until after the tracking data had been cleared off the real-time disk. The problems were of a nature that did not affect navigation but only the one-way exit occultation data. The late discovery of the bad tapes meant that the Tracking System Analysis Group had to find time to take the tracking software subsystem offline to recreate the unusable tapes, a process that required one hour per tape. These recreated occultation PTTs were successfully provided.

An additional data type was planned for the occultation in the form of 10 per second DTS data provided by DSS 14. Unfortunately, the SFOF portion of the system was not operational. The data were, however, recorded on-site, and a plan was formulated to process these data in December using an offline 360/75.

The occultation record as of November 30, 1971 was:

Number of occultations:	34
Number of successful entries:	34
Number of successful exits:	34
Rapid two-way reacquisition at exit:	29

In each instance of a single station missing entry or exit open-loop data (two DSS 41 entries, one DSS 62 exit), a second station did take good data. The two DSS 41 entries missed on open loop were caused by an error in synlo predicts, and the exit open loop missed at DSS 62 resulted from the station misinterpreting the synlo predict output.

There were five cases where the first attempt at two-way acquisition at exit occultation was unsuccessful. The first case was caused by DSS 62 being off point. The remaining four cases were a combination of frequency errors and a spacecraft receiver anomaly. The reacquisition at exit depended upon dropping the spacecraft at its rest position at enter occultation and reacquiring at exit by tuning about this rest frequency. The problem was that after about $2\frac{1}{2}$ days in orbit the spacecraft receiver's rest position shifted by 96 Hz at VCO level for no known reason. Once this anomalous shift was detected and its symptoms understood, tuning procedures were modified accordingly and all subsequent acquisitions at exit were successful.

6. Tracking system data analysis. The Tracking System Analysis Group operated a real-time DSN 360/75 pseudoresidual program that monitored tracking prediction quality as well as tracking data quality. To monitor significant events, hand plots were prepared and displayed on the predict status CCTV.

Pseudoresiduals were computed for each station pass and displayed on CCTV and on teletype at the end of each pass. The average value of the residuals for each pass was computed and plotted. Figures 31 through 48 illustrate the average two-way doppler residual and doppler noise per pass for each of the prime stations. Average residual plots over each station were computed from day 318, pass 168 (OI) through day 092, pass 307, April 1, 1972.

E. DSN Command System Analysis and Performance

1. Command activity. Command activity in support of the orbit of Mariner 9 was significantly

increased during this report period. Occasionally, delays were caused by erroneous data displays or loss of data.

In summary, the Command System performed extremely well since the update of the TCP software, which led to a great increase in operational confidence. To date, a cumulative total of 37,232 commands has been transmitted to the spacecraft. Table 9 shows the total number of commands transmitted by each DSS as of March 31, 1972. A four-month summary of command activity is shown in Table 10. The command activity summary for November 1971 is given in Volume II of the TDS Support for the MM'71 Mission.

2. System performance. The DSN Command System performed well with only three aborts during December 1971. Of these, two were caused by equipment failure and one by a procedural error. During January 1972, no aborts occurred; during February, five occurred; and none occurred in March.

Other problems were experienced which caused delays in the use of the Command System by the Project. These problems had no significant effect on the mission, but did cause periodic delays. Causes of these problems were:

- (1) 360/75 outages.
- (2) TCP I/O buffer failures.
- (3) SFOF data set failures.
- (4) HSDL outages.
- (5) TCP software anomalies.
- (6) Procedural errors.
- (7) Equipment failures.

3. System upgrade. On January 17, 1972, the 360/75 orbit support software, Model 5, was upgraded for flight support. However, it was removed from flight support after problems were noted in the Command System. The software was revised from version 24.0 to version 27.2 and again placed on flight support on January 30, 1972. However, two problems remained to be fixed:

- (1) Display of confirmation messages on DTV or TTY delayed during certain 360/75 high activity periods.
- (2) Project and NAT Command intermittently locked out of CPS during the editing process of the tracking disk file.

These two problems were corrected as soon as the required changes were approved by the Configuration Control Board and incorporated into the 360/75.

Model 5 of the 360/75 orbit support software was then revised from version 27.2 to version 27.4, and the problems were resolved.

4. Command MDR. Relatively few problems were encountered in the generation of Command MDRs after the introduction of the Model 5 software version 27.4 into the 360/75. The recovery of the command data lost before Model 5 upgrade was accomplished by having DSSs 12, 41, and 62 replay the required original data records (ODRs) during February and March 1972. Command data recovered consisted of:

- (1) 12 passes from DSS 12.
- (2) 13 passes from DSS 41.
- (3) 9 passes from DSS 62.
- (4) 2 passes from DSS 14.

The Command MDR file for Mariner 9 was then complete and up to date.

Table 1. DSN flight support/orbital operations: Mariner 9 pass chronology from orbit insertion (Nov. 14, 1971) through bi-cycle plan operations (Apr. 1, 1972)

Month	Period	DSS	Coverage (tracks)	Ranging		S/C cmds xmtd	Remarks
